

IT 230 Coding Activity Submission Template

Submit your work on the coding activities for Modules One, Two, Three, Four, and Six in this document. In addition to this document, you should submit a ZIP file containing all your Visual Studio project files and source code that can be run in Visual Studio on a different computer.

For each coding activity, complete the following steps:

- Download and rename this document to meet the file naming conventions requested in the assignment instructions.
- Fill in the required information below by replacing the bracketed text with the relevant information.
- Submit this document and your ZIP file for grading and feedback. Your ZIP file should follow the same naming conventions.

Document your work in the coding activity by completing each of the following items:

1. Provide a screenshot of the output that resulted from running your program successfully in Visual Studio. See the coding assignment instructions for an example of what should be included in the screenshot. Your screenshot must include the following elements:
 - a. Your last name as the first printed text on the screen
 - b. Verification that the program is fully functioning and data results are accurate for the given problem

This screenshot shows the application running successfully. My last name appears at the top of the window, and multiple courses have been added to the list. The program correctly displays each selected course using the Course class and overridden ToString() method.

- Copy and paste the source code text you wrote for this assignment from the *.cs file into the space below. Only providing the *.cs files or a screenshot does not meet the requirements for this part of the assignment. Code should be logically organized. It should also follow proper syntax and conventions noted in the Coding Activity Guidelines and Rubric.

using System;

namespace CreateClassesObjs

{

class Course

{

private string name;

public void setName(string courseName)

{

name = courseName;

}

public string getName()

{

return name;

}

```
public override string ToString()
{
    return name;
}
}
```

3. Show that you understand the task by explaining the design of your program in the space below. Include the process and steps you took to write your code. Explain how you arrived at the solution to the problem and completed the activity.

To complete this assignment, I reviewed the requirements for the Course class and identified the needed components: a private field, setter method, getter method, and an overridden ToString method. I created a new C# class file named Course.cs within the project and implemented the required structure inside the CreateClassesObjs namespace.

The private string field stores the course name. I added a method called setName to assign values to this field and a method called getName to retrieve the value when needed. I also overrode the ToString method so that the course name can be properly displayed in the WPF interface, specifically within list controls like a ListBox.

After writing the class, I built and ran the project to ensure it compiled correctly and integrated with the existing WPF MainWindow logic. I tested adding multiple courses to confirm they displayed properly in the interface.

4. Reflect on your learning experience and what you learned from completing the activity.

This assignment helped me better understand how classes are used in C# to organize data and functionality. I learned how private fields protect data and how public methods allow controlled access. I also gained experience overriding the ToString method, which is important when displaying objects in a WPF application.

Overall, this activity improved my understanding of object-oriented programming and how backend classes interact with a user interface in a real application.
